

Linked Lists

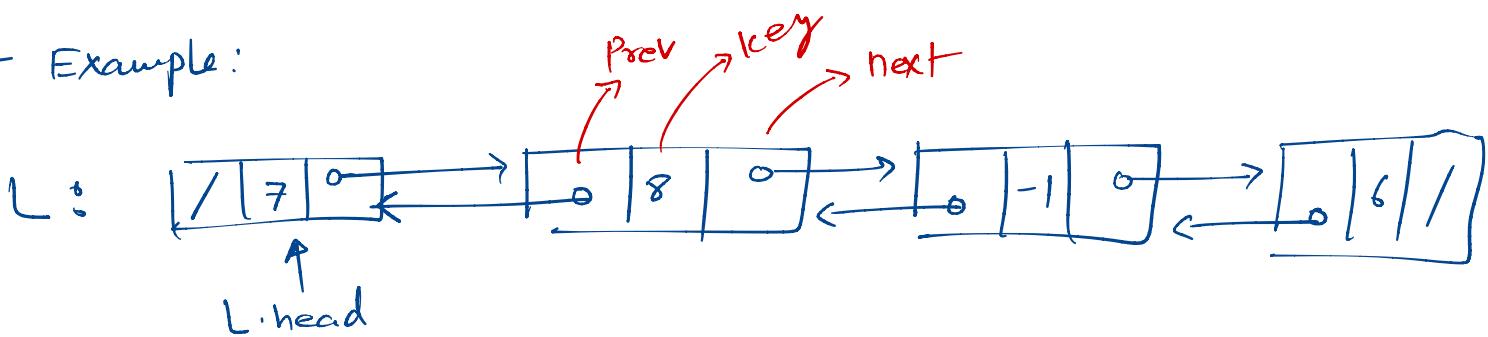

- A data structure where objects are arranged in a linear order
 - ↳ a pointer in each object determines the order
- Two types of Linked Lists (LL)
 - ↳ Singly Linked List
 - ↳ Doubly Linked List
- A doubly linked list node has attributes:
 - key : data
 - next : Pointer to next obj.
 - prev : Pointer to previous obj.

The diagram shows a rectangular box labeled 'Node' at the top. Inside the box, there are three vertical columns. The first column is labeled 'prev' with a circular arrow pointing to its right. The second column is labeled 'key' with diagonal lines through it. The third column is labeled 'next' with a circular arrow pointing to its left. Brackets above the first and third columns group them under the label 'Node'.
- For an element x :
 - $x.next$ points to the successor of x
 - $x.prev$ " " " predecessor of x
 - if $x.prev == \text{NIL}$ \Rightarrow No predecessor
 $\Rightarrow x$ is the first element of LL
↳ Head of the list
 - if $x.next == \text{NIL}$ \Rightarrow No successor
 $\Rightarrow x$ is the last element of LL
↳ Tail of the list

- A linked list may be :
 - singly or doubly
 - sorted or unsorted
 - circular or not

— Example :

— Searching a linked list

- find the first element with a given key
- Return NIL if not found

List-Search (L, k)

$x = L.\text{head}$

while $x \neq \text{NIL}$ and $x.\text{key} \neq k$

$x = x.\text{next}$

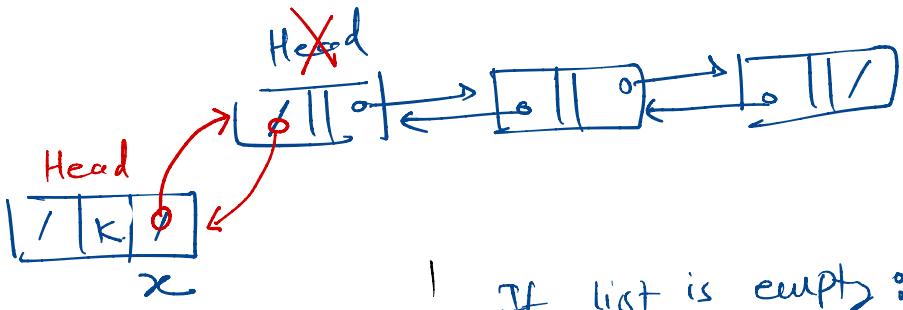

return x

$\rightarrow O(n)$

n : # of elements
in the list

— Inserting an element/node in a given linked list

a) Prepending

List-Prepend (L, x)

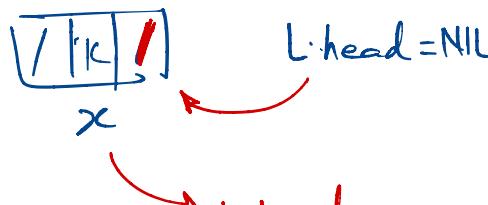

$$x \cdot \text{next} = L \cdot \text{head}$$

if $L \cdot \text{head} \neq \text{NIL}$

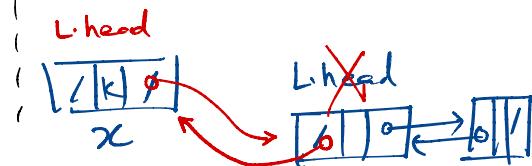

$$L \cdot \text{head} \cdot \text{prev} = x$$

$$L \cdot \text{head} = x$$

If list is empty:

If list is not empty:

List-insert (x, y) : Insert node x after node y

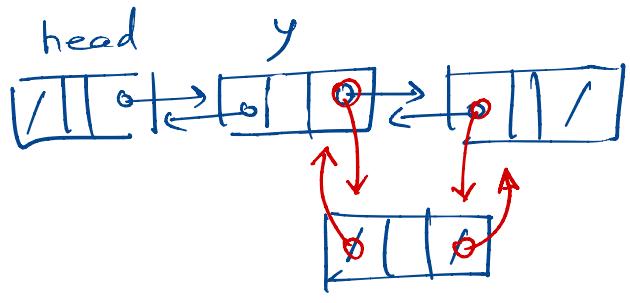

$$x \cdot \text{next} = y \cdot \text{next}$$

$$x \cdot \text{prev} = y$$

if $y \cdot \text{next} \neq \text{NIL}$

$$y \cdot \text{next} \cdot \text{prev} = x$$

$$y \cdot \text{next} = x$$

— Deleting a node from a linked list L

→ removes an element x from L

→ Splices x out of the list by updating pointers

→ First call list-Search to retrieve x for a given key

List - Delete (L, x)

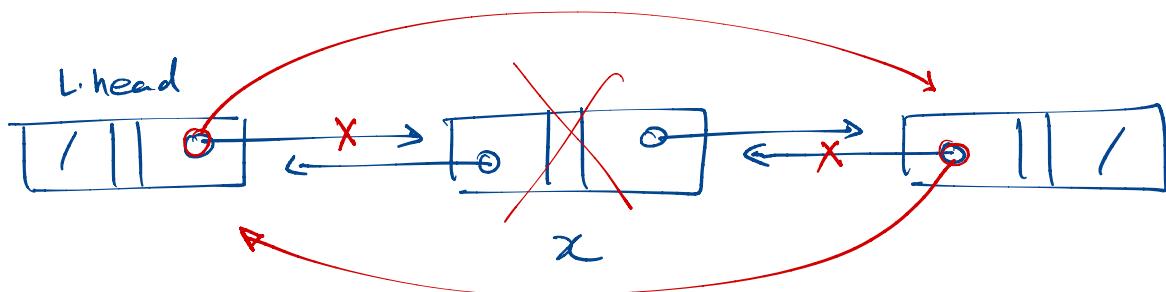

if $x.\text{prev} \neq \text{NIL}$

$x.\text{prev}.\text{next} = x.\text{next}$

else $L.\text{head} = x.\text{next}$

if $x.\text{next} \neq \text{NIL}$

$x.\text{next}.\text{prev} = x.\text{prev}$

→ Sentinels

→ a dummy object that allows simplifying boundary conditions

→ Object L.nil that represents NIL but also contains other attributes of an LL node.

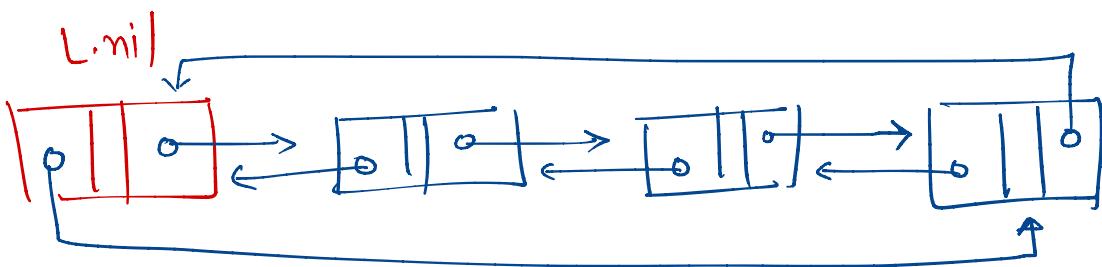

→ Replace references to NIL by L.nil

→ Turn our doubly linked list into a Circular doubly linked list

→ Sentinel L.nil lies between head & tail

⇒ L.nil.next : points to head of list

L.nil.prev : points to tail of list

List - Delete' (L, x)

List - Delete (L, x)

if $x.\text{prev} \neq \text{NIL}$
 $x.\text{prev}.\text{next} = x.\text{next}$

else $L.\text{head} = x.\text{next}$

if $x.\text{next} \neq \text{NIL}$
 $x.\text{next}.\text{prev} = x.\text{prev}$

$x.\text{prev}.\text{next} = x.\text{next}$

$x.\text{next}.\text{prev} = x.\text{prev}$

Old list - Delete without
a sentinel

List - Search' (L, k)

$L.\text{nil}.\text{key} = k$

$x = L.\text{nil}.\text{next}$

While ($x.\text{key} \neq k$)

$x = x.\text{next}$

If $x = L.\text{nil}$

return NIL

else return x

List - Insert' (x, y)

$x.\text{next} = y.\text{next}$

$x.\text{prev} = y$

$y.\text{next}.\text{prev} = x$

$y.\text{next} = x$

List - insert (x, y)

$x.\text{next} = y.\text{next}$

$x.\text{prev} = y$

if $y.\text{next} \neq \text{NIL}$

$y.\text{next}.\text{prev} = x$

$y.\text{next} = x$

Previous List - Insert
without sentinel

— No prepend function needed. In order to prepend at head, use $y = L.\text{nil}$

Todo:
Verify the claim!

→ Reversing a doubly linked list

- Swap prev & next pointers
- Assign last node to head

List - Reverse (L)

$x = L \cdot \text{head}$

while ($x \neq \text{NIL}$)

$\text{tmp} = x \rightarrow \text{prev}$

$x \cdot \text{prev} = x \cdot \text{next}$

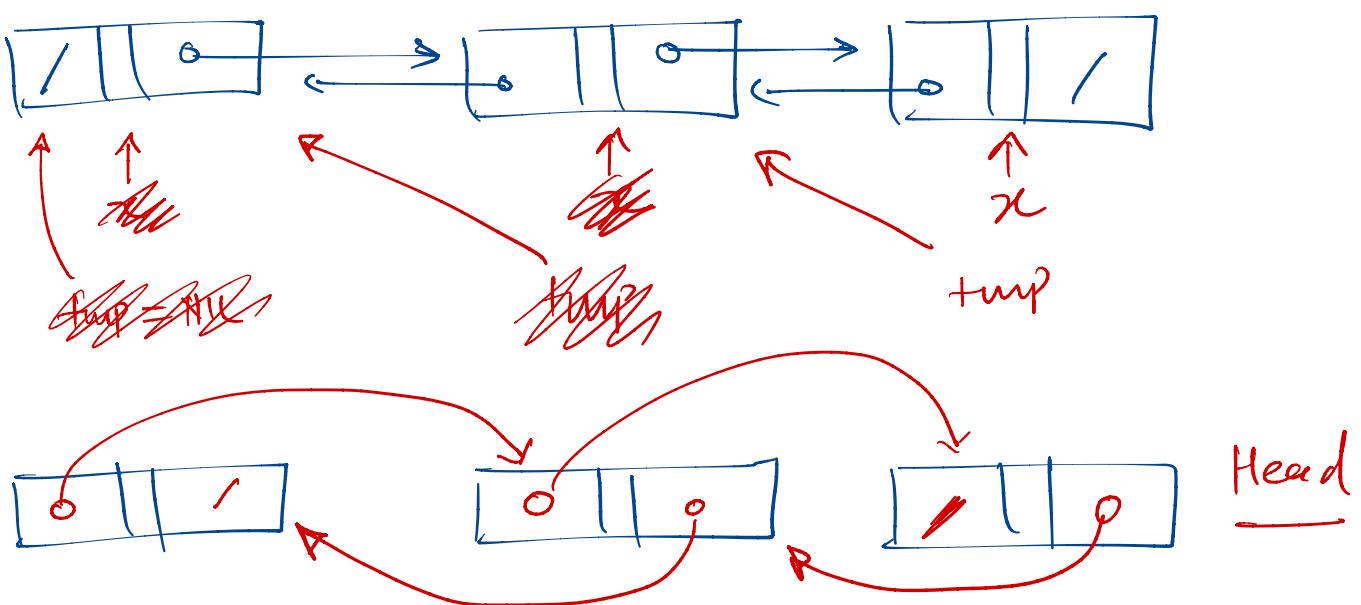

$x \cdot \text{next} = \text{tmp}$

$x = x \cdot \text{prev}$

End While

$L \cdot \text{head} = \text{tmp} \cdot \text{prev}$

Head.

→ Joining two lists

Given lists L_1 & L_2 , return
a concatenation of L_1 & L_2 .

List-Join (L_1, L_2)

$$L_1.\text{tail}.\text{next} = L_2.\text{head}$$

$$L_2.\text{head}.\text{prev} = L_1.\text{tail}$$

return $L_1.\text{head}$
